Topological properties of Hilbert schemes of almost-complex fourfolds. I. (English)

Given a smooth irreducible complex projective surface $X$, the Hilbert scheme $X^{[n]}$ of $n$ points on $X$ can be seen as a smooth resolution of the $n$-th symmetric product of $X$. Many topological properties of $X^{[n]}$ are known. The Betti numbers have been calculated by L. Göttsche [Math. Ann. 286, No. 1–3, 193–207 (1990; Zbl 0679.14007)] and only depend on the Betti numbers of $X$. This result has been clarified by H. Nakajima [Ann. Math. (2) 145, No. 2, 379–388 (1997; Zbl 0915.14001)] by constructing a representation of a Heisenberg algebra built from the rational cohomology of the surface on the direct sum $H := \bigoplus H^*(X^{[n]}, \mathbb{Q})$.

In the paper at hand, the author extends these results to Voisin’s Hilbert schemes [C. Voisin, Ann. Inst. Fourier 50, No. 2, 689–722 (2000; Zbl 0954.14002)] associated to compact almost-complex four-manifolds. He is able to prove both Göttsche’s formula and the defining commutation relations of Nakajima’s operators in this context. One main ingredient of the proof is Le Poitier’s decomposition theorem for semi-small maps (following the decomposition theorem by A. A. Beilinson, J. Bernstein and P. Deligne [Faisceaux pervers. Astérisque, vol. 100, pp. 5–171. Soc. Math. France, Paris (1982)] without using any characteristic $p$-methods or étale cohomology), which is included together with a proof as it is otherwise unpublished.

Finally, tautological bundles are defined in this almost-complex setting.
